Abstract

This paper analyses the effect of local crime rates on residents' mental health. Using longitudinal information on individuals' mental well-being, we address the problem of sorting and endogenous moving behaviour. We find that crime causes considerable mental distress for residents, mainly driven by property crime. Effects are stronger for females, and mainly related to depression and anxiety. The distress caused by one standard deviation increase in local crime is 2-4 times larger than that caused by a one standard deviation decrease in local employment, and about one seventh of the short-term impact of the 7 July 2005 London Bombings.

JEL Codes: I18, K42, R23

Keywords: neighbourhood effects, mental wellbeing, fear of crime

* We are grateful to David Card, Francesca Cornaglia, Thomas Cornelissen, Guglielmo Weber, an editor and two anonymous referees for comments and suggestions. We would like to thank participants in conferences, workshops and seminars at IAE-CSIC (Barcelona), University of Milan Bicocca, Collegio Carlo Alberto (Turin), University of Alicante and EUI (Fiesole). We acknowledge financial support from the UK Economic and Social Research Council ("Crime and mental wellbeing"; grant number: RES-000-22-1979). Fasani acknowledges the financial support of INSIDE-MOVE (Markets, Organizations and Votes in Economics), the Barcelona GSE Research Network, the Government of Catalonia (grant 2009 SGR 896), the JAE-Doc grant for the Program "Junta para la Ampliación de Estudios" co-financed by the European Social Fund and the Spanish Ministry of Science (grant ECO2011-25293). Dustmann acknowledges funding by the Norface programme on migration. Corresponding author: F. According to the Eurobarometer, crime has been among the top five concerns of European citizens in recent years, and the fight against crime is among the main priorities respondents believe their governments should have.² These concerns seem hardly justified by actual crime rates, where European countries rank very low in comparison to other parts of the world,³ which suggests that crime leads to distress for a large part of the population through channels other than direct victimisation. These indirect costs of crime, through inflicting fear and anxiety, and leading to changes in daily routines and behaviour (see e.g. Hamermesh, 1999; Braakman, 2013; Janke *et al.*, 2013), may be far larger than the direct costs. Indeed, in a recent paper, Gary Becker and Yona Rubinstein (2011) argue that major criminal acts such as terrorist attacks inflict most harm by creating fear, and by inducing changes in behaviour and individual choices. Measuring the magnitude of these indirect costs of crime is crucial for assessing the optimal investment into crime prevention. While the direct costs (response costs of police and the Criminal Justice System, and costs through the impact on victims) are routinely assessed⁴, evaluations of indirect costs, including those of non-victims, are scarce, and far more difficult.

In this paper we analyse costs of crime that are indirect and intangible. While indirect but *tangible* costs – such as changes in behaviour (not going out at night, not wearing jewellery, carrying a self-defence weapon, etc.) and investment in security (burglar alarms, armoured doors and windows, weapons, etc.) - can in principle be inferred from surveys, *intangible* costs (fear, anxiety, mental distress, etc.) are particularly difficult to measure. Our main contribution is to estimate the effect local

² Summary reports on Eurobarometer waves since 1974 can be downloaded at: http://ec.europa.eu/public_opinion/archives/eb_arch_en.htm.

³ For instance, over the last decade, EU27 countries experienced a homicide rate below 2 per 100 thousand population, which contrasts with a world estimate of almost 8 (estimated in 2004) and with average rates in Southern Africa and Central America between 20 and 30 (Harrendorf *et al.* 2010).

⁴ See Soares (2010) for a recent survey of the different approaches to estimating costs of crime. In its most recent estimation, the UK Home Office puts the cost of crime against individuals and households in the UK at about £36.2 bn in 2003/04, which amounts to about 3 % of GDP (Dubourg *et al.*, 2005). Following the methodology suggested in Dolan *et al.* (2005), these estimates carefully appraise “Physical and emotional impact on direct victims” - which accounts for about 50 % of total cost of crime. However, they do not consider the additional cost imposed by the fear of crime on the overall British society, which is one objective of this paper.

crime has on the mental health of individuals who live in the area where this crime takes place, by combining official crime statistics with detailed information on individuals' mental well-being, which we obtain from the British Household Panel Survey (BHPS) and the English Longitudinal Study of Ageing (ELSA). Both these surveys are panel surveys, which allows us to use a design that eliminates possible correlation between area crime and mental distress due to sorting of more distressed individuals into areas with higher (or lower) crime incidences. By matching each individual to detailed local-area crime statistics for various types of crimes we are able to distinguish further between the effects that particular types of crime have on mental health, thus identifying the most distressing criminal offences. We also analyse the impact of crime on different dimensions of mental health, and we study heterogeneity in responses across different groups of residents.

Our findings show a significant, and negative, impact of overall local crime rates on the mental distress of residents in urban areas. The impact is sizeable: a one standard deviation in the overall local crime rate explains between 8-15 % of the (within-individual) standard deviation in self-reported mental wellbeing. This is about twice to four times as large as the effect of a one standard deviation decrease in the areas' employment rate on mental distress. Burglary, car theft and vandalism are the crime types which seem to cause major anguish. In addition, we find heterogeneity in responses. While individuals react only to property crime when crime rates are measured in the immediate residential location, violent crime causes mental distress when including the surrounding areas, suggesting that this crime type impacts through affecting individuals' daily routines, like travel to work etc. When distinguishing between men and women, we find that women are more responsive to changes in crime rates than men. Our results based on the English Longitudinal Study of Ageing (ELSA), a data set which contains alternative measures of mental health and focuses on a particularly vulnerable group, those above the age of 50, produces very similar results.

To further assess the magnitude of our findings, we estimate the effect of the London bombings on the 7th of July 2005 on mental distress. Using a Difference-in-Difference approach, we show that in the

months following the attack citizens of London and the other major cities in the UK experienced a significant drop in their self-reported mental health. We find that the reduction in mental wellbeing following a one standard deviation increase in local crime is about one seventh of the fall in mental wellbeing caused by the London Bombings.

Our paper contributes to the literature on estimating intangible costs of crime by focusing on a new and specific aspect. While most of the previous literature has implemented either contingent valuation methods based on stated preferences (Cohen *et al.* 2004; Atkinson *et al.* 2005),⁵ or hedonic price models based on revealed preferences (Gibbons, 2004; Linden and Rockoff, 2008),⁶ our study focuses on the detrimental impact of exposure to changes in local crime on mental wellbeing of residents. Our work is also related to a recent paper by Cornaglia, Feldman and Leigh, (2014) on the relationship between mental well-being and crime for Australia.⁷ While Cornaglia, Feldman and Leigh (2014) focus most of their discussion on the difference between being victimized and being exposed to crime (but not victimized), our paper develops an in-depth analysis of the consequences for mental health of exposure to local crime.⁸

Our paper is also related to the literature on neighbourhood effects and mental wellbeing. Several non-experimental studies – almost entirely based on cross-sectional analysis - find significant associations between the mental health of residents and aspects of the neighbourhood environment.⁹

Based on the Moving to Opportunity (MTO) experiment, a randomized experiment on residential

⁵ See Hausman (2012) for a criticism of the reliability of contingent valuation methods in assessing social costs of changes in environmental quality, and a more positive assessment by Carson (2012).

⁶ Gibbons (2004) and Linden and Rockoff (2008) show that house prices fall in response to, respectively, increases in local property crime and the presence of convicted sexual offenders in the area. Similarly, Besley and Mueller (2012) look at the impact of conflict in Northern Ireland (rather than crime) and establish a negative correlation between killings and house prices.

⁷ The two papers were part of the project “Crime and mental wellbeing” supported by an ESRC grant (grant number: RES-000-22-1979).

⁸ With respect to Cornaglia, Feldman and Leigh (2014), we use two alternative datasets, three different measures of mental health and measures of crime rates at two levels of geographical disaggregation. Further, we analyse both timing and heterogeneity of the effects, consider single mental health items and single criminal offences, and benchmark the magnitude of the effects we find against the mental health consequences of a major terrorist attack.

⁹ See Mair *et al.* (2008) and Diez-Roux and Mair (2010) for recent reviews of this literature. In the UK, Propper *et al.* (2005) find a limited association between neighborhood characteristics and levels (and changes) in mental health of residents.

mobility conducted in five US cities in the 1990s, a number of studies have shown that moving away from deprived (high crime) neighbourhoods leads to significant improvements in adult physical and mental health and subjective well-being in the short- (Katz *et al.* 2001), medium- (Kling *et al.* 2007) and long-term (Ludwig *et al.* 2012).¹⁰ We add to this literature by focusing on the direct link between area crime rates and mental distress of residents who are living in the area, and by providing a precise assessment of the magnitude of these effects. We use longitudinal data and exploit repeated information on both mental wellbeing and area crime to eliminate potential sorting biases. Moreover, we analyse which specific dimensions of mental wellbeing are affected by crime, we distinguish the effects of different types of crime on mental distress, and we assess the heterogeneity in responses across different population groups.

The research we provide in this paper adds to the policy debate on the cost of mental distress to the overall society and on the role played by crime in reducing people's wellbeing. Layard (2005) argues that mental issues represent one of the biggest problems in British society, with serious consequences for the welfare system. He estimates the cost of mental illness at about 2% of GDP.¹¹ Crime is an important aggravating factor: According to the National Institute for Mental Health in England (2005), reducing fear of crime would improve mental health and well-being of Britain's populations. Following an influential independent report on health inequalities produced in the late '90s (Acheson, 1998), the British Department of Health identified decreasing exposure to crime in the neighbourhood as a crucial policy to restrict disparities in health hazard among the British population (Department of Health, 1999), and this is still a key focus of their intervention (Department of Health, 2009). Clearly, the problem is not limited to Britain. The WHO Commission on Social Determinants of Health recognized the level of crime and violence in the area of residence as an important social cause of

¹⁰ Oeropolous (2003) exploits quasi-experimental variation in assignment to different public housing projects in Toronto to estimate the impact of neighbourhood characteristics on long-term labour market outcomes of residents, but does not investigate health and mental wellbeing as possible outcomes.

¹¹ According to the Mental Health Minimum Dataset (MHMDS) in 2008-2009 about 1.2 million people (about 2.3 % of total population) were in contact with National Health Service (NHS) mental health services in England for serious mental illnesses. Individuals treated for serious mental illness are only a fraction of those suffering from mental distress.

poor health (CSDH, 2008). Our study contributes to this debate, by providing a precise assessment of the relationship between crime and mental distress.

The paper is structured as follows. Section 1 provides a brief discussion of the underlying mechanisms which link exposure to crime to mental distress, describes the data used for the empirical analysis and reports some descriptive evidence on crime and mental distress in the UK. Our main estimating equation, identification issues and empirical strategy are discussed in section 2. Section 3 reports estimation results and robustness checks. In this section, we also describe how we estimate the impact of the 2005 London bombings, present the estimates and benchmark our previous estimation results on the impact of local crime rates. Finally, the last section contains a brief discussion of our findings and some concluding remarks.

1. Background, Data and Descriptive Evidence

1.1. Local crime and mental distress

There are at least three channels through which exposure to higher crime in the area of residence may lead to mental distress: an increased level of anxiety and fear of being victimized, a reduced sense of freedom implied by limitations to behaviour (not going out at night, buying a cheaper vehicle than desired, not wearing jewellery, etc.), and the need to plan – and invest in – pre-emptive and deterrent strategies to avoid victimization (e.g. checking carefully windows and back doors when leaving home; hiding valuables; taking longer, but safer, routes to return back home; parking the car only in some areas; etc.).¹²

The extent to which actual crime rates trigger any of these channels depends on how actual crime translates into fears and perceptions about crime. A large literature in the social sciences focuses on the fear of crime (rather than crime itself; see Hale, 1996), and how perceptions of crime affect mental

¹² A more indirect effect of area crime on residents' mental distress could go through the negative effect crime produces on house prices (Gibbons, 2004). For such a mechanism to be at work, crime shocks should have a persistent effect on expectations of future area crime. We discuss this potential channel in section B2 in the online appendix.

health (see e.g. Ross and Mirowsky, 2001; Green et al, 2002; Whitley, 2005; Stafford *et al.*, 2007; Jackson and Stafford, 2009). Some authors (see e.g. Ferraro, 1995; Chadee et al. 2007; Smith and Torstensson, 1997) point out that far more people believe they are likely to be a victim of crime than actually end up being victimized. Further, groups who face low objective risks of victimisation are often more concerned about such risks; the elderly are one such example (Mawby, 1992). How actual crime rates translate into individual perceptions and fears, possibly along the channels we outline above, and are then converted into mental distress, is not what we address (and can address) in this paper. Instead, we focus here on estimating the causal effect of local area crime on mental distress of residents. It is this effect – namely, the impact a reduction of crime has on the mental distress of residents, possibly induced by a combination of the different channels discussed above, and probably amplified by individual perceptions – which is an important and relevant policy parameter.

In order to get a sense of the complexity of crime perceptions and of the role played by actual crime in shaping them, consider data for the UK. During the period we analyse in this paper (2002-2008), total recorded crime has decreased by 24 %: this reduction has been mainly driven by property crime (Figure 1). In spite of this significant fall in crime, the majority of households interviewed in the British Crime Survey believe that crime rates have increased at the national level in recent years.¹³ Indeed, as Figure 1 shows, the fraction of households who believe that crime rates have increased at the national level changed from 65 % in 2001/02 to about 75 % in 2008/09. However, respondents seem to have a more accurate assessment about crime rates in their more proximate environment. The share of households that believes crime went up in the neighbourhood is always smaller and shows a decreasing trend, dropping from 50 % in 2001/02 to about 35 % in 2008/09.

[Figure 1 approximately here]

¹³ The British Crime Survey (BCS) is a systematic victimization survey of a representative sample of people resident in England and Wales. It interviews about 50 thousand adults who are asked about their experiences and perceptions of crime. Victimization surveys usually produce estimates of total crime which are significantly larger than the levels of crime recorded by the police because they manage to capture all the criminal offences (in general, the minor ones) which are not reported to the police. Nevertheless, BCS does not allow to work with geographically detailed and quarterly crime data as we need for the analysis carried out in this paper.

Further evidence on the fact that residents are informed about crime rates in the area of residence is reported in Figure A1 (see appendix) where we have plotted the share of respondents particularly worried about a certain criminal offence (burglary, car crime and violent crime) or a risky behaviour (drug use and dealing, anti-social behaviour) against the actual crime rate of that particular offence in the PFA of residence (period 2002-2008). The positive slope of the fitted lines suggests that concern is higher in regions where crime rates are actually higher. The negative relationship in the last graph, instead, shows that respondents are more satisfied with the police intervention in areas where total crime is lower.

1.2. Data

Our empirical analysis is based on two large longitudinal surveys, the British Household Survey Panel (BHPS) which contains repeated observations on subjective measures of individual mental health for a representative sample of the British population, and the English Longitudinal Study of Ageing (ELSA), which collects similar information for a sample of individuals above the age of 50. For both datasets, we match individual records to the crime rate recorded in the months before the interview in their area of residence. Local crime data are provided by the UK Home Office.

1.2.1. British Household Survey Panel (BHPS)

The BHPS is an annual survey, which consists of a nationally representative sample of about 5,500 households, containing a total of approximately 10,000 interviewed individuals in the launch year 1991.¹⁴ A key advantage of this dataset for our purpose is that it contains rare information about mental health and general wellbeing of interviewees, which is recorded in multiple waves. Under a special permission agreement it is possible to obtain the information about the Local Authority of residence of the interviewees at the time of the interview, which allows us to match each respondent to the local crime rates and other area controls in the neighbourhood in the period before the

¹⁴ See <https://www.iser.essex.ac.uk/bhps> for more information, documentation and data access.

interview.¹⁵ Given that quarterly crime data are available since 2002, we use the BHPS waves from 2002 to 2008. Our main estimating sample comprises about 35,000 individual-year observations of residents in urban areas: this corresponds to about 9.4 thousand individuals, whom we observe on average 3.7 times. Almost 40 % of the respondents are interviewed in all six waves.

The main measure of subjective wellbeing of our empirical analysis is a 12 items version of the General Health Questionnaire (GHQ-12) which is collected in all BHPS waves. The GHQ was developed as a screening instrument for psychiatric illness but is widely used as an indicator of psychological wellbeing (Goldberg, 1978). It can detect disorders of a temporary nature such as depression and anxiety, but also permanent conditions such as schizophrenia and psychotic depression. GHQ has been used in recent studies by several economists (e.g. Clark, 2003; Gardner & Oswald, 2007; Metcalfe *et al.* 2011). The BHPS version of the GHQ has twelve questions, which are combined into a single index by assigning each response between 0 and 3 points and by then summing up across all questions (Likert scoring method).¹⁶ The highest level of distress, therefore, scores 36 and the lowest scores 0.¹⁷ In our empirical analysis, we normalize this index to range between 0 (least distressed) and 1 (most distressed).

Apart from the overall GHQ index, Graetz (1991) identifies three separate and clinically meaningful factors: anxiety and depression, social dysfunction, and loss of confidence. In our empirical analysis

¹⁵ We match individual information from the BHPS to crime data which is provided quarterly by the Home office starting from the first of January of each year. As interviews in the BHPS are collected throughout (almost) the entire year, it is not meaningful to match individuals interviewed in the first weeks of each quarter with crime rates recorded in the current quarter because most of those criminal events have not taken place at the time of the interview. We thus match interviews collected in the first two months of each quarter with crime rates in the previous quarter, while those collected in the last month of the quarter are matched with crime rates recorded in the current quarter. This implies that people interviewed between the 1st of March and the 31st of May are matched with crime recorded between the 1st of January and the 31st of March, those interviewed between the 1st of June and the 31st of August with crime recorded between the 1st of April and the 30th of June, and so on. Our results are not sensitive to changes by plus or minus 30 days in this matching rule.

¹⁶ Respondents are asked how often (on a four-point category scale) they have recently: lost sleep over worry; felt constantly under strain; felt they could not overcome difficulties; been feeling unhappy and depressed; been losing confidence; been feeling like a worthless person; were playing a useful part in things; felt capable of making decisions; been able to enjoy day-to-day activities; been able to concentrate; been able to face up to problems; and been feeling reasonably happy. See Table A 1 for more details.

¹⁷ An alternative scoring method is the "Caseness" bi-modal scoring (0-0-1-1) which gives a total scoring ranging from 0 (least distressed) to 12 (most distressed). Piccinelli *et al.* (1993) shows that the two methods are basically equivalent. All our empirical results are robust to using the "Caseness" scoring method (as in Metcalfe *et al.*, 2011) rather than the Likert one.

we adopt this disaggregation of the GHQ index, and we construct three sub-measures of mental wellbeing (GHQ – Anxiety and Depression; GHQ – Social Dysfunction; GHQ – Confidence Loss). This disaggregation allows identifying which particular dimensions of respondents’ psychology are affected. As for the main GHQ index, we normalize all these indices to range between 0 (least distressed) and 1 (most distressed). Further details on the GHQ questions and on the disaggregation in sub-indices are provided in Appendix A1.1.

In Table 1, we report detailed descriptive statistics on individual characteristics and GHQ measures, all normalised between zero (least distressed) and one (most distressed). The average level of this index is 0.31, with a median value of 0.28, an overall standard deviation of 0.15 and a within-individual standard deviation of 0.1. However, there is clear heterogeneity with respect to individual characteristics: Mental distress is slightly higher for females, increases (but not monotonically) with age, is lower for the better educated, higher for separated, divorced or widowed individuals, and higher for the unemployed or for people out of the labour force (students, maternity leave, etc.). When GHQ is disaggregated into its three components, the measure of anxiety and depression has a mean of 0.32 with standard deviation of 0.21 (within-individual standard deviation is 0.13), while the measure of “social dysfunction” is slightly higher (0.35), with standard deviation of 0.14 (within-individual standard deviation is 0.1). The measure of confidence loss, instead, is substantially lower, with an average of 0.19 and standard deviation equal to 0.23 (within-individual standard deviation is 0.13).

[Table 1 approximately here]

1.2.2. English Longitudinal Study of Ageing (ELSA)

The English Longitudinal Study of Ageing (ELSA) is an interdisciplinary biennial survey on health, economic position and quality of life, and representative for people aged 50 and above, and living in private households in England. It comprises about 12,000 respondents. ELSA has now run four waves

(2002, 2004, 2006 and 2008). Similarly to the BHPS, information on the Local Authority of residence allows us linking the survey to the crime data.

A rare feature of ELSA is the Psychosocial Health Module (PSH), surveyed in each wave, and asking respondents twelve questions about symptoms of depression. This module is one of the most common screening tests to determine individuals' depression quotient. Besides this depression index, the ELSA contains also a theory-based measure of the quality of life of older adults which consists of 19 questions (CASP-19). Although this latter measure is not exactly conceived as an index of mental wellbeing, it measures perceived general wellbeing of respondents which should reflect also their level of mental distress. Indeed, the type of questions asked to measure GHQ, PSH and CASP-19 are similar in nature (compare Table A1, Table A3 and Table A4). More details on these indices are provided in appendix A1.2. The number of respondents answering all questions of the PSH index is higher than those for the CASP index. Therefore, the sample used to study the latter is slightly larger. After matching respondents with local crime rates, our sample contains about 16,600 (PSH sample) and 13,700 (CASP-19 sample) individual-year observations. Similarly to the GHQ measures, we normalise both the PSH index and the CASP-19 index between 0 (least distressed) and 1 (most distressed).

For the population aged 50 or more, descriptive statistics from the ELSA survey for PSH and CASP-19 indexes are reported in the last rows of Table 1. As for the GHQ indexes, both PSH and CASP-19 have been normalized to vary between zero (highest wellbeing) and one (lower wellbeing). The PSH depression index has a mean value equal to 0.20, with a standard deviation equal to 0.25 and a within-individual standard deviation equal to 0.14. The mean value of the CASP-19 index, instead, is 0.27, with a standard deviation (within-individual standard deviation) equal to 0.16 (0.06).

1.2.3. *Crime Data for England and Wales*

The UK Home Office provides quarterly data by Local Authority for various types of criminal offences recorded in England and Wales.¹⁸ Over the period we analyse (2002-2008) we consistently identify 375 Local Authorities (LAs), 188 of which are urban LAs.¹⁹ The London area is split in 33 LAs. The average population in one Local Authority is about 145 thousand individuals – 110 thousand in rural and 180 thousands in urban LAs. Data can also be aggregated to 43 Police Force Areas (PFA), which reflect the territorial organization of British police forces.²⁰

Crime data are available from April 2002 and distinguish between ten categories of crime (burglary, criminal damage, drug offences, fraud and forgery, offences against vehicles, other theft offences, robbery, sexual offences, violence against person and other offences).²¹ The sum of all these items account for the “total crime” recorded in England and Wales (see Table AA 1 in the Appendix for crime definitions). We can further group these types of offences into two broader categories: “violent crime” (robbery, sexual offences, violence against person) and “property crime” (burglary, criminal damage, fraud and forgery, offences against vehicles, other theft offences).²² To compute crime rates we divide the total number of offenses in each Local Authority (or Police Force Area) by the resident population in the area (crime rates are expressed in number of offences per ten thousand population). Table 2 reports descriptive statistics on quarterly crime rates in England and Wales over the period 2002-08. The average quarterly total crime rate was about 226 crimes per 10 thousand population. This rate rises to 280 in urban LAs, with a standard deviation of 97, a within-LA standard deviation of 37 and substantial regional variation (the maximum and the minimum realizations of crime rates

¹⁸ National police forces separately record criminal offences in Scotland and Northern Ireland. Definitions and recording practices are not currently standardized at the UK level. This generates issues of comparability across countries not only for single types of crime but also for total crime rates. We therefore focus our analysis on England and Wales where data are fully comparable.

¹⁹ According to the British Office for National Statistics definition, urban LAs are defined as LAs where at least 74 % of the population lives in urban Census Output areas. A Census Output Area is urban if it has a population of over 10 thousand.

²⁰ PFA are structured such that a number of local authorities lie uniquely within a single police force area.

²¹ Police recording practice is governed by the National Crime Recording Standard (NCRS) which was introduced in all police forces in April 2002 in order to make crime recording more consistent. Before that date, data from different years and geographical locations are not directly comparable.

²² “Drug offences” and “other offences” can be considered neither violent nor property crime. They will enter in our empirical analysis only when we look at “total crime” and when we separately analyse each criminal offence.

being, respectively, 1075 in the London Borough of City of Westminster and 75 in Rochford). Property crime accounts for almost 75 % of total offenses recorded, violent crime for about 21 % and the remaining 4 % corresponds to the residual category of “total other crime”. In urban areas, the highest crime rates are recorded for “other theft” (62.5), criminal damage (57.4), violence (50.2), vehicle crime (42.4) and burglary (34.2). When considered together, these five types of criminal offence account for about 88 % of total recorded crime.

[Table 2 approximately here]

2. Empirical strategy

We estimate the following regression equation:

$$MD_{irt} = a_0 + a_1 CR_{rt} + a_2 \mathbf{Z}_{rt} + a_3 \mathbf{X}_{it} + T_t + LA_r + \eta_i + u_{irt} \quad (1)$$

where the dependent variable MD_{irt} is a measure of self-reported mental distress of individual i who lives in region r at time t . Our main variable of interest is CR_{rt} , which is the (log) crime rate in area r at time t . In our estimation, we will distinguish between different types of crime. Regional time-varying characteristics are given by \mathbf{Z}_{rt} , while \mathbf{X}_{it} are time-varying individual characteristics. Time and regional (Local Authority, LA) fixed effects are captured, respectively, by T_t and LA_r . Finally, η_i is an individual fixed effect and u_{irt} is an idiosyncratic error term.

The parameter of interest is α_1 , the effect of local crime rates on mental distress. Two problems arise in the estimation of this parameter.²³ First, sorting of individuals into residential areas may lead to a correlation between area crime rates and mental health that is not causal. Secondly, even if the sorting problem can be addressed, the parameter α_1 measures the effect of crime *and* all associated time-varying unobserved neighbourhood characteristics on mental health. While this is a causal parameter

²³ Local crime realizations are clearly exogenous to individual shocks to mental health. We assume strict exogeneity of the local crime rates, which is plausible, as a shock to individual mental health in any period is unlikely to affect area crime in the same, or in any other, period.

(if the sorting problem is solved), it does not measure the *pure* effect of crime on mental health outcomes.

Our estimation strategy deals with both these problems. Suppose first that individuals do not move across LA's over our sample period. In this case, conditioning on individual fixed effects η_i corresponds to exploiting only within-area and within-individual variation in crime and eliminates composition effects that are induced through sorting. In addition, this strategy eliminates also area effects that are correlated with both crime rates and mental health status, and that are likely to be constant over the period we consider, such as care institutions, segregation, neighbourhood composition, etc. Moreover, to capture relevant time varying neighbourhood characteristics, we condition on a large set of area characteristics. These include the LA employment rate which controls for the local economic cycle that could affect both crime rates (see Raphael and Winter-Ebmer, 2001; Gould *et al.*, 2002) and the mental health of residents (Clark and Oswald, 1994).²⁴ Further local controls include the share of residents receiving welfare benefits, the share of young adults, the share of immigrants, the number of policemen per capita, and the log population. In addition, we condition on a large set of time-varying individual controls (age, age squared, presence of children in the household, marital status, employment status, education level and log household income). Finally, we include a full set of year-quarter dummies to capture any common time effect and potential seasonality in respondents' mental wellbeing.

Some of the respondents in our sample do change area of residence during our observation window. Although movements across LA's are rare (e.g. in the BHPS sample, only about 3.4 % of respondents change Local Authority of residence every year), we address this problem by considering an individual as a different individual in each area of residence, with a different individual fixed effect, and we only use observations when the respondent has spent two consecutive periods in the same area. This

²⁴ In unreported regressions, we have checked that our results are robust to the inclusion of local unemployment - rather than employment - rates and of labour market controls at the PFA rather than LA level. Results can be provided upon request.

strategy raises two issues. First, it may create across-individuals correlation in the error terms. While this may be a concern in a cross-sectional estimation, differencing out all fixed effects should remove this potential source of across-individuals correlation. Second, and more importantly, it may introduce some selection bias in our estimation. This bias will materialise only if the decision to move to a new area in period t is affected by the crime rate in the previous residence area in period $t-1$. The sign of the bias depends on the sign of the correlation of the shocks to mental health and to the level of area dislike (which drives moving decisions), and we formally derive it in Appendix A2.

The likelihood that individuals' moves are induced by realizations of crime in the area of residence in the period before the move can be assessed. In all waves, interviewees who live in a different location than in the previous wave are asked to report the main reason of their move. Of these, only 2 % respond that the main reason was that the previous area was unsafe or unfriendly.²⁵ Crime-related moving decisions do thus not seem particularly relevant in our data.

To deal with any remaining concerns, we internalise moves by using larger spatial areas for analysis. We do that by aggregating from Local Authority level to Police Force Areas (PFAs), thus collapsing the 165 urban LAs into the corresponding 41 PFAs. This reduces the share of annual movers in our BHPS sample considerably, from about 3.4 % to 1.4 %.²⁶ Choosing larger spatial areas as unit of analysis has an added advantages: As individuals may be exposed in their daily routine to different LAs (e.g. when going to work or school, shopping, visiting relative and friends, going out, etc.), crime rates in the immediate residence area alone may be too a narrow spatial definition of crime that causes mental distress. Furthermore, crime perceptions may respond to media coverage that relates to larger areas, better captured by PFA spatial units. We will present our main results using both LA and PFA crime rates.²⁷

²⁵ Accommodation-related reasons (buying a property, being evicted, moving to smaller/larger house, etc.) account for about 45 % of the responses, followed by roughly 22 % for family-related reasons.

²⁶ Moreover, our results from the ELSA survey are exempt from this potential bias given that mobility among individuals aged 50 and over is basically zero.

²⁷ In the Online Appendix B1, we follow an alternative approach to deal with movers across spatial units. We estimate equation (1) using all available observations (rather than only using observations when the respondent has spent two

3. Results

We first report estimation results based on BHPS data. Our dependent variables are the overall GHQ and its three sub-components (GHQ-Anxiety, GHQ-Social Dysfunction and GHQ-Confidence). Our main regressor of interest is the log crime rate recorded in the area of residence of the interviewee during the last quarter before the interview.²⁸ We also present results from the ELSA sample that covers individuals aged 50 and above. In all regressions, we remove individual fixed effects by using a First Difference estimator.²⁹

3.1. *The Effects of Area Crime on Mental Distress*

Table 3 reports our main estimates for the impact of local crime on the overall GHQ measure, which has been normalized between zero (least distressed) and one (most distressed). We have normalised log crime rates by their standard deviation to ease the interpretation of our results. A positive coefficient estimate implies that an increase in crime rates in the area of residence *increases* the level of mental distress of respondents. Standard errors are robust and clustered at the same geographical level as the crime rate variable. In all regressions, we control for individual characteristics (age, age squared, a dummy for children in the household, dummies for marital status, for employment status and for education level, and log household income) and we include a full set of year-quarter dummies to capture any common time effect and potential seasonality in respondents' mental wellbeing. We always condition on the LA employment rate, but in columns 2, 4 and 6 we add further local controls in order to capture additional time-varying local characteristics.³⁰ We focus in the table (and in the

consecutive periods in the same area), and without treating individuals who move as different individuals in each location. We then use an IV type strategy, where we instrument the crime rate to which movers are exposed to with the contemporaneous crime rate in the area where they resided in the first wave of our observation window. All our empirical findings are robust to this alternative estimation strategy.

²⁸ Estimates with crime rates rather than log crime rates provide very similar results.

²⁹ We have also estimated the same models using the Within Group estimator, obtaining very similar estimates. Results can be provided upon request.

³⁰ These include: share of residents receiving benefits, share of young adults (individuals aged 15-24 over total adult population), immigrant share, number of policemen per capita and log population size. In unreported regressions, we have

reminder of the paper) on estimates obtained for urban areas only, where the upper part and lower part of the table report coefficient estimates of the (log) crime rate in the LA and PFA of residence, respectively (both measured in the quarter before the interview).³¹

[Table 3 approximately here]

The point estimates reported in the first two columns in the upper part of Table 3 suggest a positive impact in LA log total crime on individual mental distress. The coefficient is significant at the 5 % level; inclusion of additional LA controls (column 2) does not affect the estimate. When we separate violent (columns 3 and 4) and property crime (columns 5 and 6), the estimated coefficients on both types of crime are positive, but the coefficient on violent crime is substantially smaller and not significantly different from zero. The coefficient on property crime is identical to the one estimated for total crime and statistically significant. Thus, these results suggest that local crime affects mental wellbeing of residents in urban areas, and that the effect is driven mainly by property crime.

How large are these effects? The average value of the GHQ index is 0.31 with an overall standard deviation of 0.15 and a within-individual standard deviation of 0.1 (see Table 1). Thus, and assuming linearity, an estimated coefficient of 0.008 means that a one standard deviation increase in log total crime rate (or property crime rate) causes a 2.6 % increase in the GHQ index. It explains about 5.3 % of its overall standard deviation and 8 % of its within-individual standard deviation. This is a sizeable impact.

In the lower part of Table 3, we report estimates where crime rates are measured at the PFA level.

The estimated coefficients are now larger in magnitude, and more significant. We find that one

also included controls for weather conditions from the UK Met Office (maximum temperature, minimum temperature, days of air frost, total rainfall and total hours of sunshine) in the PFA of residence in the quarter before the interview. This does not affect our estimates.

³¹ We do not find a significant relationship between the GHQ index and area crime rates in rural areas, which may be related to the far lower crime rates in these areas (see Table 1), the lower population density, and the therefore lower variation of crime over time.

standard deviation increase in PFA log total crime causes a 0.014 increase in individual mental distress of residents (or 4.5 %). The coefficient is significant at the 1 % level even when all the additional LA controls are included in the regression. The coefficient on property crime is of similar magnitude and strongly significant. These regressions also show that violent crime in the area reduces mental wellbeing of residents: The coefficient estimate is about 0.005-0.006 and significant. One reason for the larger estimates when using PFA's is that the mental distress of people is related to changes in crime in an area larger than the Local Authority of residence. Indeed, as we discuss above, individuals may respond to property and violent crime outside their immediate residence area because they commute to work or they socialize outside their residence LA. Moreover, for relatively rare criminal offences such as violent crime, changes in local crime rates may be hardly observables for local residents who may instead look at larger areas in forming their expectations about victimization risk. In both cases, measuring crime on LA level may simply be too a small measure of neighbourhood crime to pick up harmful effects through mental distress. In fact, it is easy to see that including crime rates on LA level, if what matters for mental distress are crime rates on PFA level, will lead to an underestimate of the effect of crime, while including crime rates at PFA level, if what matters are crime rates at LA level, will not lead to a bias.³² Thus, throughout the paper, we will mainly focus on PFA crime rates.

To gain further insight on the magnitude of these effects we compare the estimated effects with those of the local employment rate on residents' mental well-being. The coefficient estimates in the last row show that changes in the local employment rate are significantly, and negatively, associated with changes in mental distress of residents. The estimated coefficients suggest that a 10 percentage points increase in local employment rate improves residents' mental health by about 8 % of its within-

³² To see that, consider the equation $CR_{LA} = CR_{PFA} + d_{LA-PFA}$, where CR_{LA} , CR_{PFA} are crime rates on LA and PFA level, and d_{LA-PFA} captures within-PFA variation in crime rates. Thus, d_{LA-PFA} can be thought of as a residual when regressing CR_{LA} on a set of PFA dummies, which makes it immediately clear that it is not correlated with R_{PFA} . In this special case, erroneously using CR_{PFA} as regressor while CR_{LA} should be used will lead to unbiased estimates, as the measurement error d_{LA-PFA} is not correlated with the included regressor CR_{PFA} ; however, using CR_{LA} as a regressor when CR_{PFA} is the correct measure of area crime will lead to a downward bias in estimates. See also Wooldridge 2002, p. 74.

individual standard deviation. Thus, a one standard deviation reduction in the LA (PFA) log total crime rate roughly the same amount as a 10 (20) percentage points. Given that the standard deviation of the local employment rate is just 5 percentage points, the impact of a one standard deviation decrease in the crime rate on mental health is about twice to four times as large as a one standard deviation increase in the local employment rate.

Further comparisons can be made by looking at the estimated coefficients on individual controls (reported in Table AA2 in the appendix). Consistently with the literature on the impact of major individual life events (getting married, divorcing, having a baby, being laid off, etc.) on individual happiness (see, among others: Clark *et al.*, 2008; Frijters *et al.*, 2011; Clark and Georgellis, 2013), we find strong and negative short-run effects on mental wellbeing of losing a partner, becoming unemployed or suffering a disabling injury. According to our estimates, the effect of a one standard deviation increase in the local crime rate on mental distress is about one seventh to one fifth of the short-run effect of becoming unemployed. This is quite substantial, in particular when considering that the estimates for local crime rates are the average effects for all residents, while the effects of changes in personal circumstances relate only to those who are affected.

We report some robustness checks in Table AA3, where we include, alternatively, a linear trend at the PFA level (columns 2) and at the LA level (columns 3). In addition, we test whether initial conditions in mental health, crime rates and other controls matter for the empirical relation we uncover. For each LA in our sample, we have computed initial average crime rates (total, property and violent) in year 2002. Moreover, for the period 1999-2001, we compute the average GHQ score, averages of all BHPS individual controls and averages of all LA controls used in the main specification. In column 4 to 7 of Table AA3, we progressively include these baseline LA controls interacted with year dummies in our estimating equation. In columns 8 and 9, we alternatively add to these controls a PFA and a LA linear trend. The estimates are remarkably similar across all these specifications.

3.2. *Decomposing Mental Distress Measures*

We now address the question whether the overall impact of local crime on mental distress established above is related to increased levels of anxiety and depression, or loss of self-confidence or social functionality. To do that, we use the disaggregated indicators GHQ-Anxiety and Depression, GHQ-Social Dysfunction and GHQ-Confidence Loss (see Appendix A1.1). In Table 4, we report estimates for the specification that include all controls.

If anything, one would expect exposure to crime to induce stress and anxiety, and to reduce the capability of enjoying daily activities. This direct effect could then reduce self-confidence and social interaction. Indeed, Stafford *et al.* (2007) find that individuals with pronounced fear of crime are twice as likely to suffer from depression as individuals who are less concerned about crime. In line with this, our estimates show a strong adverse effect of local crime on the level of anxiety and depression of residents. The other two dimensions – social dysfunction and confidence loss– are also affected but to a lesser extent. As before, the effects seem to be mainly driven by property crime, and estimates are larger when aggregating data up on PFA level. At that aggregation level, violent crime has also an effect on anxiety and depression as well as on confidence loss, although smaller in magnitude.³³

[Table 4 approximately here]

3.3. *Different Crime Types*

Our data distinguishes between ten different categories of crime.³⁴ This allows us to investigate more specifically which type of crime causes mental distress to residents. For the overall GHQ and its three sub-components, and using the PFA aggregation, we report estimation results in Table AA5. We find

³³ We have also broken down the GHQ index in its 12 components. Eight out of twelve of them are significantly affected by local crime rates at the PFA level, with a detrimental impact of crime on the ability to concentrate, the perception of playing a useful role in life, the feeling of being constantly under strain, the ability to overcome difficulties, the enjoyment of daily activities, the feeling of being depressed, the sense of worthiness and the level of happiness (see Table AA 4).

³⁴ These are: burglary, criminal damage, drug offences, fraud and forgery, offences against vehicles, other theft offences, robbery, sexual offences, violence against the person and other offences (see Table AA 1 for crime definitions).

strong effects on mental health of almost all property crime types, such as burglary, criminal damage, vehicle crime and “other theft”, which all significantly increase the level of mental distress of residents in the area. These types of crime account together for about 70 % of total recorded crime in the UK (see Table 2).³⁵ Moreover, we find a clear detrimental effect of violence on the mental health of people. Violence is by far the most frequent crime type in the category “violent crime”, accounting for more than 86 % of the total (Table 2). The non-significant effects of robbery and sexual crime need to be interpreted bearing in mind that these are extremely rare events. Indeed, these two criminal offences together account for less than 3 % of total recorded crime: on average, only 3 (5) individuals per 10 thousand population are victims of sexual offences (robberies) in each quarter.

When the GHQ index is decomposed into its three sub-factors, we find – as before - the largest effects on the anxiety and depression index.

3.4. Heterogeneous Effects of Crime

Different individuals may respond to crime in different ways. Indeed, both actual crime risk and fear of crime are socially stratified, with some social groups being more affected than others. Some research suggests that women and the elderly are more concerned about crime (Lagrange and Ferraro, 1989), possibly because they feel particularly vulnerable (Smith and Torstensson, 1997). The more educated may also be more aware of changes in local crime rates and, therefore, react more. On the other hand, insofar as their higher level of education reflects their income group, they may be less exposed to criminal hazard. The presence of children in the household may be an additional reason of added mental distress through area crime for parents and older relatives. To investigate whether responses are heterogeneous along these dimensions, we interact area crime rates with observed individuals characteristics and report results in Table 5.

³⁵ “Fraud and forgery”, although having a positive coefficient, is non-significant. One reason could be that this type of crime is recorded where the victims reside, but has no clear connection with the local environment (like e.g. credit card forgery).

We find a clear gender dimension in the impact of exposure to crime on mental health.³⁶ While a one standard deviation increase in log total crime causes an increase of 0.008 points in the overall GHQ index for men, the effect on women is more than twice as large. Breaking crime down into violent crime and property crime shows that the effects of property crime are similar to those of total crime, with an effect on female residents which is exactly twice as large as those on males. Moreover, the effects of violent crime discussed earlier are driven only by females, with a one standard deviation increase in the violent crime rate increasing women's overall GHQ index by about 0.008 points.

[Table 5 approximately here]

We have also investigated whether the effect of crime is more/less pronounced for those under 30, over 65, with a higher education, or living in household with children. As the estimates in Table 5 show, these interaction terms are mostly non-significant, while the gender heterogeneity is robust to their inclusion.

3.5. The Timing of the Effect of Crime on Mental Distress

Our indices of mental health are subjective and self-reported measures that refer to interviewees' assessment as to how they felt around the time of the interview along different dimension of mental wellbeing.³⁷ So far, we have shown that exposure to crime shocks in the quarter before the interview leads to lower mental wellbeing of residents. One important question is whether the effect of crime on mental distress fades away quickly, or whether it causes more persistent mental distress.

³⁶ This finding is consistent, for instance, with Frijters *et al.* (2011) who demonstrate that life satisfaction of Australian women is more strongly affected by (property) crime than that of men.

³⁷ All twelve GHQ questions use the following wording: "Have you recently....felt/been/etc.?" (see Table AA 1).

We now investigate whether previous lags of local crime rates produce a significant effect on current mental wellbeing. In addition, we test the robustness of our results to a straightforward - but powerful - falsification exercise, by regressing current mental health status on *future* crime.

Table 6 reports estimation results for total crime at the PFA level. Given that crime data start in April 2002 (see section 1.2), when working with crime lags we gradually lose observations of individuals interviewed in 2002-2003. Thus, to allow meaningful comparison of coefficients across different regressions, we restrict the sample to all those who have non-missing values for the third lag of the quarterly crime rate. This implies a 20 % reduction with respect to our main estimation sample. In the table, we define as “quarter Q” the last quarter before the interview (i.e. our main measure of crime throughout the paper), while lags (leads) are defined as, respectively, Q-1, Q-2, ... (Q+1, Q+2, ...).

The first column reports an estimate of the effect of local crime recorded in the last quarter before the interview on mental wellbeing of residents. The coefficient is almost identical to our baseline estimate reported in Table 3. We then include lags and leads of crime, each one at a time (columns 2-6) and all of them together (column 7). There seems to be some persistence of the effect: the first and second lags of crime (columns 2-3) have a sizeable and significant effect on current mental wellbeing, but the effect disappears with the third lag (column 4). Instead, future realizations of crime do not explain current mental health (columns 5-6). In column 7, we include current crime, as well as all leads and lags. The estimated coefficients for quarter Q is identical in magnitude (although the standard error is slightly larger), remaining unaffected by the inclusion of the other crime controls. All the other coefficients, instead, are smaller, and far from significant.

[Table 6 approximately here]

In our dataset, adjacent changes in quarterly crime rates are strongly correlated (correlation is about 0.7), suggesting the existence of local crime cycles that last more than one quarter, which may suggest

that it is meaningful to consider more than one quarter as a time window to crime exposure. We have done this in the last three columns of the table, where we have repeated the same analysis using six-month intervals (average crime rate over two quarters) rather than single quarters (columns 8-10).³⁸ The pattern we observe does not change: crime rate in the six months before the interview (column 8) produces a sizeable and significant detrimental effect on mental health, while crime rate 6-12 months before the interview does not seem to have any effect (column 9). Taken together, these findings suggest that fluctuations in local crime produce a temporary effect on subjective mental wellbeing of residents.

We find further evidence of the temporariness of this effect by investigating the impact of local crime on more permanent measures of mental health and on the overall health of the interviewees. The BHPS questionnaire includes questions on whether respondents suffer from depression or anxiety among their main health problems, whether they are addicted to alcohol or drugs, and whether they visited a psychotherapist during the last year. The BHPS also records both a subjective assessment of health status and more objective measures such as whether the respondent went to see her GP or she was in-patient/out-patient at the hospital in the last year. We have run regressions using our main specification, but replacing GHQ indices with each of these outcomes as dependent variable. We find no significant relationship between any of these outcomes and crime rates recorded in the last three, six or twelve months before the interview. Estimation results can be provided upon request.

All this evidence points at exposure to crime being a stressful but temporary event, which creates mental distress in the short run, but has no immediate repercussions on more permanent mental conditions, subjective health, or attendance of health services. The temporariness of the effect we identify is fully consistent with the existing literature on wellbeing which shows that individuals tend to adapt fairly quickly to major individual life events such as getting married, divorcing, having a baby,

³⁸ When six-month periods are considered rather than quarters, the correlation between contiguous changes in crime rate drops from 0.7 to 0.3.

being laid off, etc., see for instance work by Clark and Georgellis (2013), Clark *et al.* (2008) and Frijters *et al.* (2011). However, temporariness of the effects does not imply that exposure to crime in the area of residence can be disregarded. Rather, although area crime may not have persistent effects on mental distress, it is a repeated shock: different from other personal lifetime events that occur rarely, residents are permanently exposed to temporary crime shocks. Even if individuals fully recover after each shock, this implies that in any given period there will be a sizeable fraction of the population – those living in areas hit by negative crime shocks – who is more mentally distressed than in the absence of such shocks. This may have important consequences for their behavior, relationships and productivity.³⁹

3.6. Results using the English Longitudinal Study of Ageing

We now turn to the data from the English Longitudinal Study of Ageing (ELSA), focussing on people aged 50 and above. ELSA contains two alternative measures of mental wellbeing: a depression index (PSH), and a measure of quality of life of older adults (CASP-19). To check the robustness of our results, we replicate our previous analysis using this alternative dataset and measures of mental wellbeing.⁴⁰ Table 7 reports FD estimates of regressing the PSH and the CASP-19 indices on local crime in the LA (upper part of the table) or PFA (lower part of the table) of residence. In spite of the differences in data, sample and measure of mental distress, our empirical findings are fully consistent with our previous results. Local crime increases mental distress of residents, with property crime seemingly playing a larger role. In particular, the depression index PSH is significantly higher for individuals exposed to higher crime: a one standard deviation increase in total crime in the LA of residence increases the PSH index by 0.024 points. This implies a 12 % increase with respect to its mean value

³⁹ Although our setting does not allow us to identify the cumulative impact of having being exposed to repeated temporary crime shocks, the evidence from the Moving to Opportunity (MTO) experiment, shows that moving away from deprived areas – i.e. areas where individuals are more exposed to crime shocks - leads to significant improvements in both subjective and objective well-being (Katz *et al.* 2001; Kling *et al.* 2007; Ludwig *et al.* 2012).

⁴⁰ Given the age profile of the respondents, residential mobility is almost non-existent in the ELSA dataset: in each period, between 0 and 0.3 % of interviewees have changed LA of residence with respect to the previous wave.

(0.2) and would explain up to 17 % of its within-individual standard deviation (0.14). Similarly, a one standard deviation increase in crime raises the CASP index by 0.008 points, which corresponds to a 3 % increase with respect to its mean value (0.27) and to 13 % of its within-individual standard deviation (0.06). Very similar coefficients are found for PFA crime rates.

[Table 7 approximately here]

In unreported regressions, we have looked at which specific crime types produce the strongest negative impact on resident mental wellbeing. Consistently with the evidence from the BHPS data discussed above (section 3.3), we find the largest and more significant coefficients for burglary, vehicle crime and violence.⁴¹

3.7. Assessing the Magnitude of Crime Effects

How large is the effect of being exposed to exogenous changes in local crime rates on individuals' mental health? We gave a first answer to this question by comparing our estimates with the impact of the local employment rate (see section 3.1), and the impact of changes in personal circumstances, such as becoming unemployed. In this section we investigate this aspect further, by contrasting the effects of changes in local crime rates to the effect to a major violent terrorist attack which had a dramatic impact on the UK: the 7 July 2005 London bombings. This was a series of coordinated suicide attacks on London's public transport system during the morning rush hours. The different explosions killed 52 people and injured about 700. The attacks were completely unexpected and represented the first terrorist act of Muslim extremists in the UK. The impact of this event on British residents was quite dramatic.⁴²

⁴¹ Results can be provided upon request.

⁴² Rubin *et al.* (2005) and Rubin *et al.* (2007) illustrate the impact on stress and perceived threat as well as travel behaviour among Londoners in the aftermath of the event. Similar negative effects on mental wellbeing have been observed among the American population after the 9/11 attacks (Stein *et al.*, 2004).

The BHPS data allow us to investigate the impact the 7/7 attack had on UK residents' self-reported mental health, as interviews are carried out throughout the entire year, so that, in 2005, some individuals have been interviewed before, and some after that event. Unfortunately, the immediate period before and after the terrorist attack is not covered by the data, as interviews routinely stop in May and start again in September (see Table AA6). We make use of a Difference in Difference (DID) approach to identify the effect of interest. A similar identification strategy has been implemented with BHPS data by Metcalfe *et al.* (2011) to estimate the effect of the September 11 attacks on the subjective wellbeing of the British population.

We identify the causal impact of the London Bombing on British citizens' mental health by comparing those interviewed in the months preceding the bombing with those interviewed in the months following the event. Our identification strategy assumes that the timing of the interview – with respect to the date of the London bombings – is random. A first concern arises from the possibility that interviewers could manipulate the date of their interview in response to the London bombings. This seems unlikely as the terrorist attack – by definition – was unexpected and there is no reason to expect it to have affected the scheduled timings of BHPS interviews.⁴³ In any case, if individuals more negatively affected by the 7/7 attack refused to answer the BHPS questionnaire in the months after the event, we would estimate a lower bound of the overall effect. A second, more relevant, problem with this identification strategy is seasonality in responses: mental distress may differ in different months during the year. If autumn and winter months have a detrimental effect on mental wellbeing, then at least part of the increase in mental distress after the 7/7 bombings could be driven by this seasonal effect. We remove these effects by combining the before-after analysis with a DID approach, comparing the difference in 2005 (before and after July) with that measured in the year before (2004).⁴⁴ We thus estimate the following regression:

⁴³ In addition, BHPS does not carry out interviews during the summer (Table AA 6). Thus, the possible disruptions in the interview schedule by the terrorist attack in its immediate aftermath are not a concern here.

⁴⁴ Including year 2003 does not substantially alter our findings. We do not use years after 2005, because permanent changes – such as the permanently higher levels of alert described in the previous section – may confound the effects.

$$MD_{it} = \beta_0 + \beta_1 AfterJuly_i + \beta_2 year2005_i + \beta_3 (AfterJuly * year2005)_i + v_{it} \quad (2)$$

Here MD_{it} is the level of mental distress of individual i at time t . We identify the treated group with a dummy variable $Year2005$ which is equal to one if the interview was carried out in 2005 (rather than in 2004). The “treatment” dummy $AfterJuly$, instead, is equal to one if the interview took place after July. The coefficient of interest is β_3 , which is equal to one for those individuals interviewed between September and December in 2005 (that is, in the aftermath of the bombing). As before, we use as dependent variable the mental wellbeing measured by GHQ (or by its sub-components: anxiety, social dysfunction and confidence). Alternatively, we use the residuals from regressing GHQ measures on individual characteristics, Local Authority fixed effects and year and month dummies.⁴⁵ Our design should randomise individuals across all these characteristics. Indeed, using either measure leads to basically the same results, which is what one would expect if respondents’ characteristics are orthogonal with respect to the date of the interview. In all regressions, we cluster the standard errors by local authority of residence to allow for any possible correlation in the mental distress shocks of individuals living in the same area.

We report results of our DID estimates in Table 8. We start by looking at all LAs. We then progressively restrict the sample to the main 20 cities (in terms of population), the main 5 cities and, finally, Greater London (which contains 33 Local Authorities).⁴⁶ In each case, our dependent variable is first the GHQ index and then the residual GHQ. In the third column of each sample we restrict the observations of those interviewed “after July” only to the interviews collected in September (rather than using the period September-December).⁴⁷ In the last three columns, instead, we look at the three (residual) GHQ subcategories (still using only individuals interviewed in September in the “after July” group).

⁴⁵ As in our previous analysis, individual controls are: gender, age, age squared, a dummy for children in the household, dummies for marital status, employment status, categorical variables for education level, and log household income.

⁴⁶ The main 20 cities are: Birmingham, Bradford, Bristol, Cardiff, Coventry, Derby, Kingston-upon-Hull, Leeds, Leicester, Liverpool, London, Manchester, Newcastle upon Tyne, Nottingham, Plymouth, Sheffield, Southampton, Stoke-on-Trent, Swansea, and Wolverhampton. The main 5 cities are: Birmingham, Bradford, Leeds, London and Sheffield.

⁴⁷ The limited simple size of those interviewed in the first six month of the year, does not allow us to restrict the control group only to individuals interviewed in May (see Table AA 6).

In all regressions, we find a positive coefficient on β_3 , suggesting that, in the aftermath of the London bombings, individuals reported a higher level of mental distress. The coefficient increases in size and becomes strongly significant when we restrict the sample to the main 20 cities, the main 5 cities, or just London. Thus, the impact of the London bombings is larger on urban residents who are more exposed to the risk of a terrorist attack. Results for GHQ or residual GHQ are almost identical, as are results we obtain when we drop individuals interviewed between October and December. Finally, columns 3-6 show that most of the impact seems to be on anxiety and depression. This is similar to the results we find for overall crime. There are also sizeable effects on Social Dysfunction, but no significant effect on Confidence Loss – again, similar to what we find for local area crime.

When we focus on the main 5 cities and on Greater London, in the months immediately following the bombing, the self-reported mental distress increased by roughly 0.1 points, implying that the GHQ index increased by more than 30 % with respect to its mean value (which is about 0.3); this accounts for about 65 % of its standard deviation (and for 100 % of its within standard deviation).

[Table 8 approximately here]

How large are the effects of crime changes in the area of residence in comparison to those we find for the London bombing? We report above that a one standard deviation increase in log crime rates implies an increase in the GHQ index of 0.014 points. This implies that a one standard deviation change in the local crime rate on residents' mental wellbeing is about 1/7 of that induced by the 2005 London bombing in the months immediately following the terrorist attack. This is sizeable, given the dramatic effect the London bombing had on the British population. Moreover, while the London bombing was a one-off incident, changes in local crime happen on a continuous scale.

4 Conclusions

In this paper, we analyse the indirect and intangible costs of crime, through inflicting mental distress, depression and anxiety, on individuals who live or work in the vicinity where crime takes place. We exploit detailed panel data on mental wellbeing from two longitudinal surveys and we find that local crime rates have a significant, negative, and substantial effect on mental well-being in urban areas. While most of this effect works through property crime, violent crime turns out to be important when we increase the area within which crime is recorded. This suggests that - while property crime concerns individuals mostly when committed in their immediate neighbourhood - violent crime is also relevant for the mental distress of citizens when it takes place in a larger spatial area around their habitation. We benchmark our results with the impact on mental health of British citizens of local unemployment rates, and the London bombings in July 2005. We show that the effect of a one standard deviation increase in the crime rate on mental health is about twice to four times as large as a one standard deviation increase in the local employment rate; and about one seventh of the impact of the London bombing – which was a dramatic event. We conclude that the effects of local crime on mental distress of citizens are large, with possibly significant economic costs. Thus, crime reduction and crime prevention may have benefits far beyond those typically suggested.

Year-quarter dummies	X	X	X	X	X	X
Other LA controls		X		X		X
Observations	25,647	25,647	25,647	25,647	25,647	25,647

Note. This table reports FD estimates of GHQ index on log crime rates recorded during the quarter before the interview in, respectively, the LA (upper part of the table) or PFA (lower part of the table) of residence. The GHQ index has been normalized to vary between 0 (least distressed) and 1 (most distressed). Other controls are: individual controls (age, age squared, a dummy for children in the household, dummies for marital status, for employment status and for education level, and log household income); a full set of year-quarter dummies; employment rate in the LA of residence (yearly average); other LA controls (share of residents receiving welfare benefits, share of individuals aged 15-24 over total adult population, immigrants share, number of policemen per capita and log population size).

Sample: BHPS data. Urban LAs.

Standard errors: robust and clustered by LA (upper part of the table; 165 clusters) or by PFA (lower part of the table; 41 clusters); *significant at 10%; **significant at 5%; ***significant at 1%.

Table 4 - Mental Health and Crime: Disaggregating GHQ into Anxiety, Social Dysfunction and Confidence

	1	2	3	4	5	6	7	8	9	10	11	12
	GHQ - Overall			GHQ - Anxiety and Depression			GHQ - Social Dysfunction			GHQ - Confidence Loss

log (property crime rate)			0.015*** [0.005]			0.020** [0.008]			0.014*** [0.005]			0.010 [0.007]
Individual controls	X	X	X	X	X	X	X	X	X	X	X	X
Year-quarter dummies	X	X	X	X	X	X	X	X	X	X	X	X
All LA controls	X	X	X	X	X	X	X	X	X	X	X	X
Observations	25,647	25,647	25,647	25,647	25,647	25,647	25,647	25,647	25,647	25,647	25,647	25,647

Note. This table reports FD estimates of the four GHQ indices (Overall, Anxiety and Depression, Social Dysfunction; Confidence Loss) on log crime rates recorded during the quarter before the interview in, respectively, the LA (upper part of the table) or PFA (lower part of the table) of residence. All four GHQ indices have been normalized to vary between 0 (least distressed) and 1 (most distressed). Other controls are: individual controls (age, age squared, a dummy for children in the household, dummies for marital status, for employment status and for education level, and log household income); a full set of year-quarter dummies; employment rate in the LA of residence (yearly average); all LA controls (employment rate, share of residents receiving welfare benefits, share of individuals aged 15-24 over total adult population, immigrants share, number of policemen per capita and log population size). Each row reports results from a separate regression, with total crime, violent crime and property crime included alternatively in the regression. Sample: BHPS data. Urban LAs.

Standard errors: robust and clustered by LA (upper part of the table; 165 clusters) or by PFA (lower part of the table; 41 clusters); *significant at 10%; **significant at 5%; ***significant at 1%.

Note. This table reports FD estimates of GHQ index on log total crime rates recorded during the months before the interview in the PFA of residence. The GHQ index has been normalized to vary between 0 (least distressed) and 1 (most distressed). In the table, we define as “quarter Q” the last quarter before the interview (i.e. our main measure of crime throughout the paper), while lags (leads) of crime rate are defined as, Q-1, Q-2, ... (Q+1, Q+2, ...). Other controls are: individual controls (age, age squared, a dummy for children in the household, dummies for marital status, for employment status and for education level, and log household income); a full set of year-quarter dummies; all LA controls (employment rate, share of residents receiving welfare benefits, share of individuals aged 15-24 over total adult population, immigrants share, number of policemen per capita and log population size).

Sample: BHPS data. Urban LAs.

Standard errors: robust and clustered by PFA (41 clusters); *significant at 10%; **significant at 5%; ***significant at 1%.

Observations	1,262	1,262	695	695	695	695

Note. This table reports DID estimates of the impact of the 2005 London Bombings on GHQ index (and its subcategories) of respondents. The dummy variable "Year2005" is equal to one if the interview was carried out in 2005 (rather than in 2004) and identifies the treatment group. The dummy "After July" is equal to one if the interview took place after July and identifies the "treatment". In columns 1-2, this includes individuals interviewed between September and December (included), while in columns 3-6 we restrict it only to interviews collected in September. The table reports the coefficient estimated on the interaction between the "Year2005" dummy and the "After July" dummy, which is equal to one for those individuals interviewed after July in 2005. The GHQ indices have been normalized to vary between 0 (least distressed) and 1 (most distressed). Residual GHQ measures are obtained computing the residuals after regressing GHQ measures on individual characteristics (gender, age, age squared, a dummy for children in the household, dummies for marital status, for employment status and for education level, and log household income), Local Authority fixed effects and year and month dummies. Main 20 cities are: Birmingham, Bradford, Bristol, Cardiff, Coventry, Derby, Kingston-upon-Hull, Leeds, Leicester, Liverpool, London, Manchester, Newcastle upon Tyne, Nottingham, Plymouth, Sheffield, Southampton, Stoke-on-Trent, Swansea, and Wolverhampton. Main 5 cities are: Birmingham, Bradford, Leeds, London and Sheffield. London (inner and outer) includes 33 LAs. Each cell reports estimation results from a separate regression.

Sample: BHPS data. Years 2004-2005.

Standard errors: robust and clustered by LA; *significant at 10%; **significant at 5%; ***significant at 1%.

Appendix

A1 Measures of Mental Health

A1.1 BHPS: The General Health Questionnaire (GHQ-12)

The GHQ-12 questionnaire administered in the BHPS is as follows:

Table A 1 – GHQ-12 Questionnaire

Have you recently....	1) Been able to concentrate on whatever you are doing?
	2) Lost much sleep over worry?
	3) Felt that you were playing a useful part in things?
	4) Felt capable of making decisions about things?
	5) Felt constantly under strain?
	6) Felt that you couldn't overcome your difficulties?
	7) Been able to enjoy your normal day-to-day activities?
	8) Been able to face up to your problems?
	9) Been feeling unhappy and depressed?
	10) Been losing self-confidence in yourself?
	11) Been thinking of yourself as a worthless person?
	12) Been feeling reasonably happy, all things considered?
Answer:	less than usual / no more than usual / rather more than usual / much more than usual

While the longer versions of the GHQ are normally considered multidimensional, the GHQ-12 is often regarded as measuring only a single dimension of psychological health. However, several authors suggested that the GHQ-12 contained two or three clinically meaningful factors. Following Graetz's (1991) disaggregation of GHQ-12 into three factors - a) anxiety and depression; b) social dysfunction; c) loss of confidence) - GHQ-12 questions can be grouped in the following way:

Table A 2 – GHQ-12 Disaggregation

Anxiety and depression	2) Lost much sleep over worry?
	5) Felt constantly under strain?

	6) Felt that you couldn't overcome your difficulties? 9) Been feeling unhappy and depressed?
Social dysfunction	1) Been able to concentrate on whatever you are doing? 3) Felt that you were playing a useful part in things? 4) Felt capable of making decisions about things? 7) Been able to enjoy your normal day-to-day activities? 8) Been able to face up to your problems? 12) Been feeling reasonably happy, all things considered?
Loss of confidence	10) Been losing self-confidence in yourself? 11) Been thinking of yourself as a worthless person?

A1.2 Measures of mental health in ELSA

A1.2.1 ELSA Psychosocial Health Module (PSH)

The ELSA Psychosocial Health Module (PSH) assesses symptoms of depression, based on the Centre for Epidemiologic Studies Depression Scale (CES-D), which is one of the most common screening tests for helping an individual to determine his or her depression quotient (Radloff, 1977). Interviewees are asked whether they recently had symptoms of depression (feeling of unhappiness, loneliness, fatigue, etc.). An index of depression can be constructed by assigning one point for each positive answer (and zero for negative ones). The measure ranges between 0 (least distressed) and 8 (most distressed). In our empirical analysis we normalize the variable to range between 0 (least distressed) and 1 (most distressed).

The PSH questions in ELSA are the following:

Table A 3 - Psychosocial Health Module (PSH)

Much of the time during the past week...	1) ... have you felt depressed?
	2) ... you felt that everything you did was an effort?
	3) ... your sleep was restless?

	4) ... you were happy?
	5) ... you felt lonely?
	6) ... you enjoyed life?
	7) ... you felt sad?
	8) ... you could not get going?
Answer:	yes / no

A1.2.2 CASP-19

The ELSA contains also a theory-based measure of the quality of life of older adults which consists of 19 questions (CASP-19). Although this latter measure is not exactly conceived as an index of mental wellbeing, it measures perceived general wellbeing of respondents which should reflect also their level of mental distress. Indeed, the type of questions asked to measure GHQ, PSH and CASP-19 are very similar in nature.

CASP-19 is a theory-based measure of the quality of life of older adults (Hyde *et al.*, 2003), which consists of 19 questions (CASP-19). Although this latter measure is not exactly conceived as an index of mental wellbeing, it measures perceived general wellbeing of respondents which should reflect also their level of mental distress. Indeed, the type of questions asked to measure GHQ, PSH and CASP-19 are very similar in nature (compare Table A 1, Table A 3 and Table A 4). The CASP-19 questions cover four theoretical domains: a) Control: the ability to intervene actively in one's own environment; b) Autonomy: the feeling of an individual to be free from unwanted interference by others; c) Self-realisation: the active processes of human fulfilment; d) Pleasure: the sense of fun derived from the more active aspects of life.

The CASP-19 measure takes account of whether or how often (often, sometimes, not often or never) statements on the four domains of quality of life apply to older people. A scale is created that ranges from 0, which represents total satisfaction on all domains, to 57, which represents a complete absence of quality of life. In our empirical analysis we adopt the Likert scoring method and we normalize the

variable to range between 0 (least distressed) and 1 (most distressed). The CASP-19 questionnaire is the following:

Table A 4 - CASP-19

Control	1) My age prevents me from doing the things I would like to 2) I feel that what happens to me is out of my control 3) I feel free to plan for the future 4) I feel left out of things
Autonomy	5) I can do the things that I want to do 6) Family responsibilities prevent me from doing what I want to do 7) I feel that I can please myself what I do 8) My health stops me from doing things I want to do 9) Shortage of money stops me from doing the things I want to do
Pleasure	10) I look forward to each day 11) I feel that my life has meaning 12) I enjoy the things that I do 13) I enjoy being in the company of others 14) On balance, I look back on my life with a sense of happiness
Self-realization	15) I feel full of energy these days 16) I choose to do things that I have never done before 17) I feel satisfied with the way my life has turned out 18) I feel that life is full of opportunities 19) I feel that the future looks good for me
Answer:	often / sometimes / not often / never

A2 Identification and Empirical Issues

We estimate the following regression, where, we have written the region index r as a function of the individual i and time t , and where the dependent variable $\widetilde{MD}_{ir(i,t)t}$ are the residuals after time changing region- and individual characteristics, and time dummies have been netted out:

$$\widetilde{MD}_{ir(i,t)t} = a_0 + a_1 CR_{r(i,t)t} + LA_{r(i,t)} + \eta_i + u_{ir(i,t)t} \quad (1A)$$

Suppose we estimate this equation in First Differences. For individuals who do not move across LAs, the FD transformation removes both the LA and individual fixed effects:

$$\Delta \widetilde{MD}_{ir(i,t)t} = \alpha_1 \Delta CR_{r(i,t)t} + \Delta u_{ir(i,t)t} \quad (2A)$$

The parameter α_1 can be consistently estimated given that $cov(\Delta CR_{r(i,t)t}, \Delta u_{ir(i,t)t}) = 0$.

For individuals who moved from region r to region r' , instead, we have:

$$\widetilde{MD}_{ir'(i,t)t} - \widetilde{MD}_{ir(i,t-1)t-1} = \alpha_1 (CR_{r'(i,t)t} - CR_{r(i,t-1)t-1}) + (\varepsilon_{ir'(i,t)t} - \varepsilon_{ir(i,t-1)t-1}) \quad (3A)$$

where: $\varepsilon_{ir'(i,t)t} = LA_{r'(i,t)} + u_{ir'(i,t)t}$ and $\varepsilon_{ir(i,t-1)t-1} = LA_{r(i,t-1)} + u_{ir(i,t-1)t-1}$.

Therefore, first differencing will only eliminate the area fixed effects for *non-movers*, while for *movers* the error term contains the difference in the area fixed effects of the two locations, which may be correlated with the difference in crime rates across the two locations. This will introduce a bias in our estimates whose sign is ambiguous (it depends on the relative size of the correlations between crime realizations and LA fixed effects within and across areas).

The main strategy we employ to address this identification problem is to consider an individual as a different individual in each area of residence, with a different individual fixed effect. We thus only use observations when the respondent has spent two consecutive periods in the same area. However, this approach may introduce some selection bias in our estimation: if moving decisions are affected by past crime rates, individuals who did not move in response to a given realization of crime must have received shocks to their moving decision different from those who moved somewhere else. If shocks to mental distress and to moving decisions are correlated, this will potentially bias our estimates.

To see this, we start by modelling the moving decision. An individual i living in area r in time period t will move away ($m_{irt} = 1$) from that area if her level of unobserved dislike for the area (m_{irt}^*) is above a certain threshold \bar{m}_i . Suppose that the moving decision in one period depends on the level of crime recorded in the region in the previous period:

$$m_{irt} = 1 \text{ if } m_{irt}^* > \bar{m}_i \quad (4A)$$

$$m_{irt}^* = \beta_0 + \beta_1 CR_{rt-1} + \phi_i + v_{irt} \quad (5A)$$

Now, when estimating equation (1A) using only “stayers”, we obtain consistent estimates if:

$$\begin{aligned} & E[(CR_{irt} - CR_{irt-1})(u_{irt} - u_{irt-1}) | m_{irt} = m_{irt-1} = 0] = \\ & = E[(CR_{irt} - CR_{irt-1})(u_{irt} - u_{irt-1}) | v_{irt} \leq \bar{m}_i - \beta_0 - \beta_1 CR_{rt-1} - \phi_i; v_{irt-1} \leq \bar{m}_i - \beta_0 - \beta_1 CR_{rt-2} - \phi_i] = 0 \end{aligned} \quad (6A)$$

This is the case if shocks to dissatisfaction with the area and to mental distress are not correlated (i.e. $E(u_{irt}, v_{irt}) = 0$). Note that this allows the unobserved individual-specific term η_i in equation (1A) to be correlated with the term ϕ_i in equation (5A), which should eliminate most sources of correlation due to individual specific heterogeneity. However, if moving decisions are affected by past crime rates (i.e. $\beta_1 \neq 0$), and if u_{irt} and v_{irt} are correlated, then estimates based on “stayers” may be biased. The sign of the bias depends on the correlation between the shocks u_{irt} and v_{irt} . Assume that shocks affecting area dislike are positively correlated with shocks that determine mental distress. Now suppose that crime was very high in area r in the last period. People who decide not to move away from area r must have experienced a low shock v_{irt} to their level of dislike of the area in the current period. By focusing only on “stayers” we may thus create a negative correlation between CR_{rt-1} and v_{irt} . If u_{irt} and v_{irt} are positively correlated, this implies a negative correlation between CR_{rt-1} and u_{irt} which can potentially create an upward bias in our estimates. Indeed, if we compute:

$$\begin{aligned} & E(\Delta CR_{rt}, \Delta u_{irt} | m_{irt} = m_{irt-1} = 0) = E(CR_{rt}, u_{irt} | m_{irt} = m_{irt-1} = 0) - \\ & E(CR_{rt}, u_{irt-1} | m_{irt} = m_{irt-1} = 0) - E(CR_{rt-1}, u_{irt} | m_{irt} = m_{irt-1} = 0) + \\ & E(CR_{rt-1}, u_{irt-1} | m_{irt} = m_{irt-1} = 0) \end{aligned} \quad (7A)$$

even if the first, second and last term in the summation are equal to zero, the third conditional covariance is negative $E(CR_{rt-1}, u_{irt} | m_{irt} = m_{irt-1} = 0)$. This implies that:

$$E(\Delta CR_{rt}, \Delta u_{irt} \mid m_{irt} = m_{irt-1} = 0) > 0 \quad (8A)$$

Therefore, if moving decisions are actually affected by past crime rates (i.e. $\beta_1 \neq 0$), and if u_{irt} and v_{irt} are positively correlated, our estimates may be upward biased.

As we discuss in section 2, we consider this a minor concern given that crime-related moving decisions do not seem particularly relevant in our data. Indeed, in the online appendix B1 we use an IV strategy to deal with this potential concern, where we instrument the crime rate to which movers are exposed to with the contemporaneous crime rate in the area where they resided in the first wave. The estimation results of this alternative strategy fully confirm our main results.

A3 Appendix figures

Fig. A 1 – Concern about Crime and Risky Behaviour, Rating of Local Police and Local Crime, by PFA; BCS data (2004-2008)

Note. Authors' calculations from British Crime Survey (BCS) data and UK Home Office recorded crime statistics.

A4 Appendix Tables

Table AA 1 - Crime Categories: Definitions and Crime Sub-Categories List

	Crime type	Definition	Crime list (subcategories)
Violent crime	Robbery	A robbery is an incident or offence in which force or the threat of force is used either during or immediately prior to a theft or attempted theft. As with violence against the person, police recorded robberies cover a wide range of seriousness from armed bank robberies to muggings for mobile phones or small amounts of money.	1) Robbery of business property. 2) Robbery of personal property.
	Sexual offences	The group of other sexual offences recorded by the police covers unlawful sexual activity, mostly involving consenting adults and is therefore particularly influenced by police activity in investigating such crime.	1) Most serious sexual crime. a) Sexual assault on a male aged 13 and over; b) Sexual assault on a male child under 13; c) Rape of a female aged 16 and over; d) Rape of a female child under 16; e) Rape of a female child under 13; f) Rape of a male aged 16 and over; g) Rape of a male child under 16; h) Rape of a male child under 13; i) Sexual assault on a female aged 13 and over; j) Sexual assault on a female child under 13; k) Sexual activity involving a child under 13; l) Causing sexual activity without consent; m) Sexual activity involving a child under 16; n) Sexual activity etc. with a person with a mental disorder; o) Abuse of children through prostitution and pornography; p) Trafficking for sexual exploitation. 2) Other sexual offences. A) Incest or familial sexual offences; b) Exploitation of prostitution; c) Abduction of a female; d) Soliciting for the purpose of prostitution; e) Abuse of position of trust of a sexual nature; f) Sexual grooming; g) Other miscellaneous sexual offences; h) Unnatural sexual offences; i) Exposure and voyeurism.
	Violence (Violence against the person)	Violence against the person offences contain the full spectrum of assaults, from pushing and shoving that result in no physical harm, to murder. Even within the same offence classification, the degree of violence varies considerably between incidents.	1) Violence against the person - with injury. a) Murder; b) Manslaughter; c) Infanticide; d) Homicide; e) Attempted murder; f) Intentional destruction of a viable unborn child; g) Causing death by dangerous driving; h) Causing death by careless driving when under the influence of drink or drugs; i) Causing death by careless or inconsiderate driving; j) Inflicting Grievous Bodily Harm (GBH) with intent; k) Use of substance or object to endanger life; l) Possession of items to endanger life; m) Inflicting Grievous Bodily Harm (GBH) without intent; n) Racially or religiously aggravated inflicting Grievous Bodily Harm (GBH) without intent; o) Causing death by aggravated vehicle taking; p) Causing or allowing death of a child or vulnerable person; q) Causing death by driving; unlicensed drivers etc.; r) Corporate Manslaughter; s) Actual Bodily Harm (ABH) and other injury; t) Racially or religiously aggravated Actual Bodily Harm (ABH) or other injury; u) Poisoning or female genital mutilation. 2) Violence against the person - without injury. a) Conspiracy to murder; b) Threats to kill; c) Endangering railway passengers; d) Endangering life at sea; e) Possession of firearms with intent; f) Possession of other weapons; g) Possession of article with blade or point; h) Harassment; i) Public fear, alarm or distress; j) Racially or religiously aggravated harassment; k) Racially or religiously aggravated public fear, alarm or distress; l) Cruelty to and neglect of children; m) Abandoning a child under the age of two years; n) Child abduction; o) Procuring illegal abortion; p) Assault without injury on a constable; q) Assault without injury; r) Racially or religiously aggravated assault without injury.
Property crime	Burglary	The police record an offence of burglary if a person enters any building as a trespasser and with intent to commit an offence of theft, Grievous Bodily Harm (GBH) or unlawful damage.	a) Burglary in a dwelling; b) Attempted burglary in a dwelling; c) Distraction burglary in a dwelling; d) Attempted distraction burglary in a dwelling; e) Aggravated burglary in a dwelling; f) Burglary in a building other than a dwelling; g) Attempted burglary in a building other than a dwelling; h) Aggravated burglary in a building other than a dwelling.
	Criminal damage	Police recorded criminal damage results from any person who without lawful excuse destroys or damages any property belonging to another, intending to destroy or damage any such property or being reckless as to whether any such property would be destroyed or damaged.	a) Arson endangering life; b) Arson not endangering life; c) Criminal damage to a dwelling; d) Criminal damage to a building other than a dwelling; e) Criminal damage to a vehicle; f) Other criminal damage; g) Racially or religiously aggravated criminal damage to a dwelling; h) Racially or religiously aggravated criminal damage to a building other than a dwelling; i) Racially or religiously aggravated criminal damage to a vehicle; j) Racially or religiously aggravated other criminal damage; k) Threat or possession with intent to commit criminal damage.
	Fraud and Forgery	Under the Fraud Act 2006, fraud is defined as dishonestly making a false representation to obtain property or money for themselves or another.	a) Fraud by company director; b) False accounting; c) Cheque and credit card fraud (pre Fraud Act 2006); d) Preserved other fraud and repealed fraud offences (pre Fraud Act 2006); e) Fraud by false representation: cheque, plastic card and online bank accounts; f) Fraud by false representation: other frauds; g) Fraud by failing to disclose information; h) Fraud by abuse of position; i) Obtaining services dishonestly; j) Making or supplying articles for use in fraud; k) Possession of articles for use in fraud; l) Bankruptcy and insolvency offences; m) Forgery or use of false drug prescription; n) Other forgery; o) Possession of false documents; p) Vehicle/driver document fraud.
	Vehicle crime (Offences against vehicles)	The police recorded crime category of offences against vehicles covers private and commercial vehicles (although does not distinguish between the two).	a) Aggravated vehicle taking; b) Theft from a vehicle; c) Theft or unauthorised taking of motor vehicle; d) Interfering with a motor vehicle.
	Other theft	The recorded crime offence group of other theft offences covers thefts that are not covered by other property crime offence groups (i.e. thefts from vehicles is included in offences against vehicles).	a) Profiting from or concealing knowledge of the proceeds of crime; b) Theft from the person; c) Theft in a dwelling other than from automatic machine or meter; d) Theft by an employee; e) Theft of mail; f) Dishonest use of electricity; g) Theft or unauthorised taking of a pedal cycle; h) Shoplifting; i) Theft from automatic machine or meter; j) Other theft or unauthorised taking; k) Handling stolen goods.
Other Crime	Drug offences	Recorded crime figures for drugs offences refer to any act involving trafficking, dealing and possession of illicit drugs	a) Trafficking in controlled drugs; b) Other drug offences; c) Possession of controlled drugs (excluding cannabis); d) Possession of controlled (cannabis).
	Any other crime	Other miscellaneous offences	a) Possession of firearm; b) Other firearms offences; c) Concealing an infant death close to birth; d) Bigamy; e) Going equipped for stealing, etc.; f) Blackmail; g) Kidnapping; h) Treason; i) Riot; j) Violent disorder; k) Other offences against the State and public order; l) Perjury; m) Libel; n) Betting, gaming and lotteries; o) Aiding suicide; p) Immigration offences; q) Perverting the course of justice; r) Absconding from lawful custody; s) Customs and Revenue offences; t) Bail offences; u) Trade description offences; v) Health and Safety offences; w) Obscene publications, etc. and protected sexual material; x) Protection from evictions; y) Adulteration of food; z) Other knives offences; aa) Public health offences; ab) Planning laws; ac) Disclosure, obstruction, false or misleading statements etc.; ad) Other indictable or triable-either-way offences; ae) Dangerous driving.

share of benefit claimants			-0.434 [0.380]		-0.431 [0.485]
share of residents aged 15-24			-0.688* [0.379]		-0.653* [0.375]
share of immigrants			0.062 [0.071]		0.068 [0.060]
police officer per capita			-0.506 [0.594]		-0.307 [0.506]
log (resident population)			0.014 [0.133]		-0.001 [0.125]
Other individual controls		X	X	X	X
Year-quarter dummies		X	X	X	X
Observations		25,647	25,647	25,647	25,647

Note. This table reports FD estimates of GHQ index on log crime rates recorded during the quarter before the interview in, respectively, the LA (columns 1-2) or PFA (columns 3-4) of residence. The GHQ index has been normalized to vary between 0 (least distressed) and 1 (most distressed). "Other individual controls" are: age, age squared, a dummy for children in the household, categorical variables for education level, and log household income.

Sample: BHPS data. Urban LAs.

Standard errors: robust and clustered by LA (upper part of the table; 165 clusters) or by PFA (lower part of the table; 41 clusters); *significant at 10%; **significant at 5%; ***significant at 1%.

Observations	25,647	25,647	25,647	25,647	25,635	25,635	24,661	24,661	24,661

Note. This table reports FD estimates of GHQ index on log crime rates recorded during the quarter before the interview in, respectively, the LA (upper part of the table) or PFA (lower part of the table) of residence. The GHQ index has been normalized to vary between 0 (least distressed) and 1 (most distressed). A linear trend is included at the PFA level (columns 2 and 8) or at the LA level (columns 3 and 9). "Initial LA crime rates" is the average crime rate (respectively, total, property and violent) in the LA of residence in year 2002 interacted with year dummies. "Initial avg GHQ (LA)" is the average GHQ in the LA of residence measured over the period 1999-2001 and interacted with year dummies. "Initial avg BHPS controls (LA)" are the averages of individual controls in the LA of residence measured over the period 1999-2001 and interacted with year dummies. "Initial LA controls" are the average LA controls measured over the period 1999-2001 and interacted with year dummies. Other controls are: individual controls (age, age squared, a dummy for children in the household, dummies for marital status, for employment status and for education level, and log household income); a full set of year-quarter dummies; employment rate in the LA of residence (yearly average); all LA controls (employment rate, share of residents receiving welfare benefits, share of individuals aged 15-24 over total adult population, immigrants share, number of policemen per capita and log population size). Each cell reports results from a separate regression, with total crime, violent crime and property crime included alternatively in the regression.

Sample: BHPS data. Urban LAs.

Standard errors: robust and clustered by LA (upper part of the table; 165 clusters) or by PFA (lower part of the table; 41 clusters); *significant at 10%; **significant at 5%; ***significant at 1%.

Table AA 4 - Mental Health and Crime: Single GHQ Items

GHQ item:	1) Unable to concentrate	3) Playing useful role	5) Constantly under strain	6) Unable to overcome difficulties	7) Enjoy day-to-day activities	9) Feeling unhappy or depressed	11) Feeling worthless	12) Not feeling reasonably happy
log (total crime rate)	0.017* [0.008]	0.017** [0.008]	0.016** [0.007]	0.021*** [0.007]	0.017** [0.007]	0.022** [0.010]	0.012* [0.007]	0.016** [0.006]
log (violent crime rate)	0.005 [0.005]	0.005 [0.004]	0.004 [0.005]	0.011** [0.004]	0.006 [0.004]	0.011** [0.005]	0.007** [0.003]	0.008** [0.003]

		In (Any other crime rate)	0.004 [0.003]	0.006 [0.004]	0.001 [0.003]	0.008** [0.004]
	Individual controls			X	X	X
Year-quarter dummies			X	X	X	X
all LA controls			X	X	X	X
Observations			25,647	25,647	25,647	25,647

Note. This table reports FD estimates of the four GHQ indices (Overall, Anxiety and Depression, Social Dysfunction; Confidence Loss) on log crime rates recorded during the quarter before the interview in the PFA of residence. All four GHQ indices have been normalized to vary between 0 (least distressed) and 1 (most distressed). Other controls are: individual controls (age, age squared, a dummy for children in the household, dummies for marital status, for employment status and for education level, and log household income); a full set of year-quarter dummies; employment rate in the LA of residence (yearly average); all LA controls (employment rate, share of residents receiving welfare benefits, share of individuals aged 15-24 over total adult population, immigrants share, number of policemen per capita and log population size). Each cell reports estimation results from a separate regression. Sample: BHPS data. Urban LAs.

Standard errors: robust and clustered by PFA (41 clusters); *significant at 10%; **significant at 5%; ***significant at 1%.

Table AA 6 - BHPS: number of interviews by year and month

Interview Month	Year 2004	Wave	Year 2005	Wave	Year 2006	Wave
January	84	14	167	15	131	16
February	42	14	58	15	23	16
March	17	14	12	15	19	16
April	9	14	6	15	1	16
May	0	14	3	15	0	16
Total (Jan-May)	152		246		174	
September	4,168	15	4,952	16	5,226	17
October	3,196	15	3,064	16	2,976	17
November	1,291	15	931	16	789	17
December	272	15	176	16	127	17
Total (Sept-Dec)	8,927		9,123		9,118	

Note. Authors' calculations from BHPS data.
